1 Activity: Debug Python Code

1.1 Introduction

One of the biggest challenges faced by analysts is ensuring that automated processes run smoothly. Debugging is an important practice that security analysts incorporate in their work to identify errors in code and resolve them so that the code achieves the desired outcome.

Through a series of tasks in this lab, you'll develop and apply your debugging skills in Python.

Tips for completing this lab

As you navigate this lab, keep the following tips in mind:

- **### YOUR CODE HERE ###** indicates where you should write code. Be sure to replace this with your own code before running the code cell.
- Feel free to open the hints for additional guidance as you work on each task.
- To enter your answer to a question, double-click the markdown cell to edit. Be sure to replace the “[Double-click to enter your responses here.]” with your own answer.
- You can save your work manually by clicking File and then Save in the menu bar at the top of the notebook.
- You can download your work locally by clicking File and then Download and then specifying your preferred file format in the menu bar at the top of the notebook.

1.2 Scenario

In your work as a security analyst, you need to apply debugging strategies to ensure your code works properly.

Throughout this lab, you'll work with code that is similar to what you've written before, but now it has some errors that need to be fixed. You'll need to read code cells, run them, identify the errors, and adjust the code to resolve the errors.

1.3 Task 1

The following code cell contains a syntax error. In this task, you'll run the code, identify why the error is occurring, and modify the code to resolve it. (To ensure that it has been resolved, run the code again to check if it now functions properly.)

```
[2]: # For loop that iterates over a range of numbers
      # and displays a message each iteration

      for i in range(10):
          print("Connection cannot be established")
```

```
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
Connection cannot be established
```

Hint 1

The header of a for loop in Python requires specific punctuation at the end.

Hint 2

The header of a for loop in Python requires a colon (:) at the end.

Question 1 What happens when you run the code before modifying it? How can you fix this?

Before modifying the code, the display lets us know that there is an error in the python coding. The error is within the header of the for loop that is missing a colon : at the end. Once we add that, we can see that the connection cannot be established which means it is not functioning properly.

1.4 Task 2

In the following code cell, you're provided a list of usernames. There is an issue with the syntax. In this task, you'll run the cell, observe what happens, and modify the code to fix the issue.

```
[3]: # Assign `usernames_list` to a list of usernames

      usernames_list = ["djames", "jpark", "tbailey", "zdutchma", "esmith",
                        ↪ "srobinso", "dcoleman", "fbautist"]

      # Display `usernames_list`

      print(usernames_list)
```

```
['djames', 'jpark', 'tbailey', 'zdutchma', 'esmith', 'srobinso', 'dcoleman',
'fbautist']
```

Hint 1

Each element in `usernames_list` is a username and should be a string. In Python, a string should have quotation marks around it.

Hint 2

When creating a list in Python, the elements of the list should be separated with commas. There should be a comma between every two consecutive elements.

Question 2 What happens when you run the code before modifying it? How can you fix it?

Before modifying the code we get a `SyntaxError`. This lets us know that there is an error in line 3, which is because the usernames do not have quotation marks around the usernames and the elements of the list are not separated with commas.

1.5 Task 3

In the following code cell, there is a syntax error. Your task is to run the cell, identify what is causing the error, and fix it.

```
[5]: # Display a message in upper case  
  
print("update needed".upper())
```

UPDATE NEEDED

Hint 1

Calling a function in Python requires both opening and closing parentheses.

Hint 2

In the code above, check that each function call has both opening and closing parentheses.

Question 3 What happens when you run the code before modifying it? What is causing the syntax error? How can you fix it?

Before modifying the code, there is a syntax error that lets us know there is an error in line 3. When we call functions in Python, we need to use both opening and closing parentheses. In the code above there is no closing parentheses and once we add the closing parentheses, we see the output “UPDATE NEEDED”.

1.6 Task 4

In the following code cell, you’re provided a `usernames_list`, a `username`, and code that determines whether the username is approved. There are two syntax errors and one exception. Your task is to find them and fix the code. A helpful debugging strategy is to focus on one error at a time and run the code after fixing each one.

```
[11]: # Assign `usernames_list` to a list of usernames that represent approved users

usernames_list = ["djames", "jpark", "tbailey", "zdutchma", "esmith",
    ↪ "srobinso", "dcoleman", "fbautist"]

# Assign `username` to a specific username

username = "esmith"

# For loop that iterates over the elements of `usernames_list` and determines
    ↪ whether each element corresponds to an approved user

for name in usernames_list:

    # Check if `name` matches `username`
    # If it does match, then display a message accordingly

    if name == username:
        print("The user is an approved user")
```

The user is an approved user

Hint 1

In Python, the = assignment operator allows you to assign or reassign a variable to a value, and the == comparison operator allows you to compare one value to another (or the value of one variable to the value of another).

Hint 2

Indentation is important in Python syntax. Check that the indentation inside the for loop and the indentation inside the if statement are correct.

Hint 3

Check that each time a variable is used, it's spelled in the same way it was spelled when it was assigned.

Question 4 What happens when you run the code before modifying it? What is causing the errors? How can you fix it?

Before modifying the code, it lets us know that there is a syntax error, in line 16. However there are multiple things causing the error. The first is that username_list is missing an s, usernames_list. The second is that in Python the = allows us to assign a variable to a value and the ==comparison aoperator allows you to compare one value to another. You also need to indent the print to ensure that indentation is correct.

1.7 Task 5

In this task, you'll examine the following code and identify the type of error that occurs. Then, you'll adjust the code to fix the error.

```
[1]: # Assign `usernames_list` to a list of usernames

usernames_list = ["elarson", "bmoreno", "tshah", "sgilmore", "eraab"]

# Assign `username` to a specific username

username = "eraab"

# Determine whether `username` is the final username in `usernames_list`
# If it is, then display a message accordingly

if username == usernames_list[4]:
    print("This username is the final one in the list.")
```

This username is the final one in the list.

Hint 1

Recall that indexing in Python starts at 0.

Hint 2

Identify how many elements there are in the `usernames_list`.

Hint 3

Since indexing in Python starts at 0 and the `usernames_list` contains 5 elements, identify which index value corresponds to the final element in `usernames_list`.

Question 5 What happens when you run the code before modifying it? What type of error is this? How can you fix it?

`IndexError`, list index out of range is what the output runs. Since indexing in Python should start at '0', and the `usernames_list` contains '5' elements, we need to correctly identify that the `usernames_list` should only contain 4 elements which correctly identify the index value of the final element in `usernames_list`.

1.8 Task 6

In this task, you'll examine the following code. The code imports a text file into Python, reads its contents, and stores the contents as a list in a variable named `ip_addresses`. It then removes elements from `ip_addresses` if they are in `remove_list`. There are two errors in the code: first a syntax error and then an exception related to a string method. Your goal is to find these errors and fix them.

```
[7]: # Assign `import_file` to the name of the text file

import_file = "allow_list.txt"

# Assign `remove_list` to a list of IP addresses that are no longer allowed to
    ↳ access the network

remove_list = ["192.168.97.225", "192.168.158.170", "192.168.201.40", "192.168.
    ↳ 58.57"]

# With statement that reads in the text file and stores its contents as a list
    ↳ in `ip_addresses`

with open(import_file, "r") as file:
    ip_addresses = file.read()

# Convert `ip_addresses` from a string to a list

ip_addresses = ip_addresses.split()

# For loop that iterates over the elements in `remove_list`,
# checks if each element is in `ip_addresses`,
# and removes each element that corresponds to an IP address that is no longer
    ↳ allowed

for element in remove_list:
    if element in ip_addresses:
        ip_addresses.remove(element)

# Display `ip_addresses` after the removal process

print(ip_addresses)
```

```
['ip_address', '192.168.25.60', '192.168.205.12', '192.168.6.9',
'192.168.52.90', '192.168.90.124', '192.168.186.176', '192.168.133.188',
'192.168.203.198', '192.168.218.219', '192.168.52.37', '192.168.156.224',
'192.168.60.153', '192.168.69.116']
```

Hint 1

A with statement in Python requires a colon (:) at the end of the header.

Hint 2

The `.split()` method in Python is used on strings to convert them to lists. To call the `.split()` method, place the string you want to split in front of the method call.

Question 6 What happens when you run the code before modifying it? What is causing the errors? How can you fix them?

Before modifying the code, we get a `SyntaxError` letting us know that there are errors in the code. What is causing them is that the `with` statement in Python requires a colon at the end of the header and it is missing, as well as the `.split()` being misplaced in front of the `ip_addresses` instead of behind. You can fix them by adding them and rewriting to ensure the code is properly output.

1.9 Task 7

In this final task, there are three operating systems: OS 1, OS 2, and OS 3. Each operating system needs a security patch by a specific date. The patch date for OS 1 is "March 1st", the patch date for OS 2 is "April 1st", and the patch date for OS 3 is "May 1st".

The following code stores one of these operating systems in a variable named `system`. Then, it uses conditionals to output the patch date for this operating system.

However, this code has logic errors. Your goal is to assign the `system` variable to different values, run the code to examine the output, identify the error, and fix it.

```
[11]: # Assign `system` to a specific operating system as a string

system = "OS 2"

# Assign `patch_schedule` to a list of patch dates in order of operating system

patch_schedule = ["March 1st", "April 1st", "May 1st"]

# Conditional statement that checks which operating system is stored in
# `system` and displays a message showing the corresponding patch date

if system == "OS 1":
    print("Patch date:", patch_schedule[0])

elif system == "OS 2":
    print("Patch date:", patch_schedule[1])

elif system == "OS 3":
    print("Patch date:", patch_schedule[2])
```

Patch date: April 1st

Hint 1

Recall that indexing in Python starts at 0.

Hint 2

Note that the patch dates in `patch_schedule` are in order of operating system. The first patch date in `patch_schedule` corresponds to OS 1, the second patch date in `patch_schedule` corresponds to OS 2, and so on.

Hint 3

Since indexing in Python starts at 0 and `patch_schedule` is in order of operating system from OS 1 to OS 3, the index value 0 corresponds to the patch date for OS 1, the index value 1 corresponds to the patch date for OS 2, and so on.

Question 7 What happens when you run the code before modifying it? What is causing the logic errors? How can you fix them?

Before modifying the code, the system is assigned to OS2 but the putput does not match the correct patch date for OS2. There are a few mistakes before fixing it which do not coorelate with the correct date. When we assing OS1 to the correct date, the correct date would be March 1st. This is because these are logic errors and to fix them we need to use the correct `patch_schdudles` to coorelate with the correct date.

1.10 Conclusion

What are your key takeaways from this lab?

Key takeaways involve an activity in debugging to fix errors in code. Python common erros include, Syntax errors (:, missing ',') logic erros when the logic used in code produces unintended results, exceptions errors, an exception is an error that involves code that cannot be executed even though it is syntactically correct. Keep in mind that if you have multiple errors, the Python interpreter will output error messages one at a time, starting with the first error it encounters. After you fix that error and run the code again, the interpreter will output another message for the next syntax error or exception it encounters.

When dealing with syntax errors, the error messages you receive in the output will generally help you fix the error. However, with logic errors and exceptions, additional strategies may be needed.
